Water Use in the California Residential Home

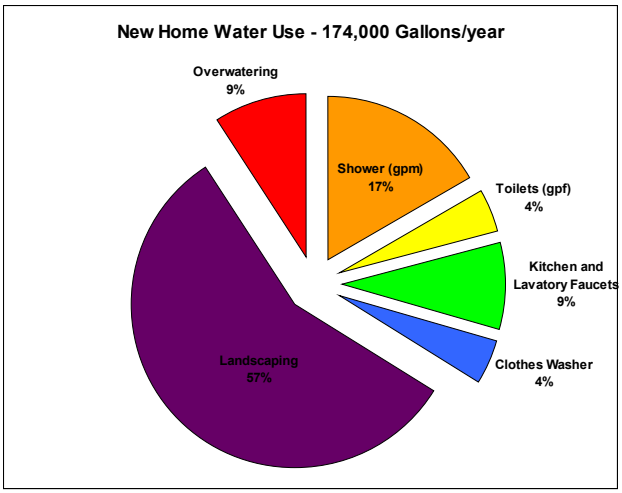
Prepared for: California Homebuilding Foundation
Date published: January 26, 2010
Prepared By: ConSol

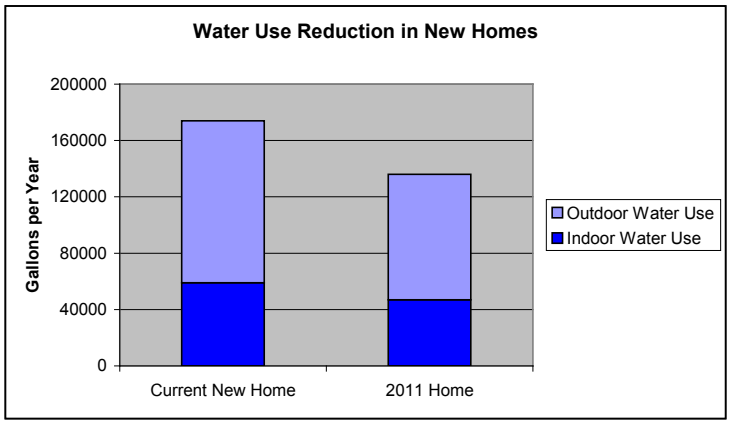
Executive Summary:
A new three bedroom single family home with four occupants is modeled to use 174,000 gallons of water per year. The majority of this water use is due to landscaping. The largest indoor water use is by showers. These estimates are based on assumptions provided in the California Green Building Standards Code (CGBSC) and the California Department of Water Resources' Model Water Efficient Landscape Ordinance.

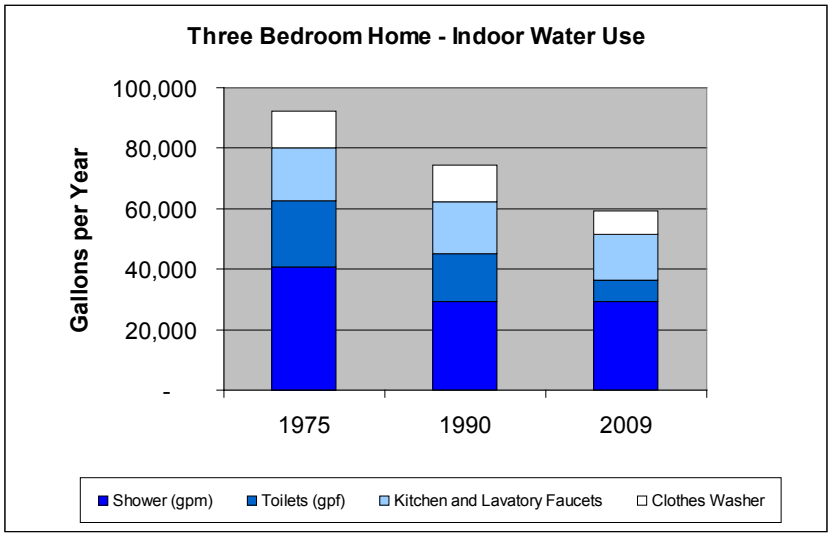


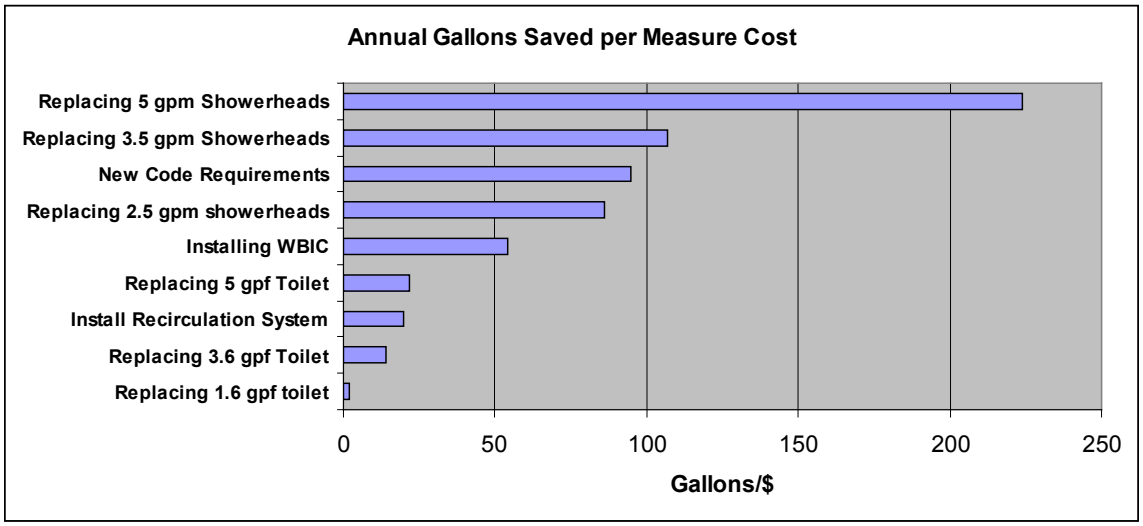
The CGBSC will come into effect in 2011, combined with the Model Ordinance; homes built to these standards will save approximately 38,000 gallons of water per year. One of the largest sources of these savings is the use of Weather Based Irrigation Controllers, which have been shown to reduce the amount of landscape over-watering by 85%, and total household water use by 7%

While there is still significant savings potential in new California homes, older California homes represent an even greater opportunity. Changes in code requirements in 1980 and 1992 have served to reduce the indoor water use of a three bedroom home by 35% over the last 30 years. Old toilets and showerheads can use up to three times more water than current available models.

Addressing existing housing, particularly old showerheads, can be a very cost effective way of reducing water use. Additionally, in order to achieve deep reductions in the amount of water used in homes, strategies must be developed to reach the 7,500,000 existing single family homes and the 13,000,000 total housing units in the state.







Lastly, the single largest use of water in the United States is by electric power plants. By continuing to improve the energy efficiency of homes, California home builders are indirectly helping to reduce nationwide water consumption.

Table of Contents

Water Use in the United States

Water is becoming an increasingly important resource throughout California and the United States. The largest single use of water use is in the cooling towers of power plants, followed by water used to irrigate for agriculture. Combined, these two uses account for over 80% of all domestic water use. The largest remaining segment of water use is that of Public Water Supplies. As of the year 2000, 85% of the national and 89% of California's population received their drinking water from public supplies; the remainder relies on self supplied water sources, generally ground water wells. Figure 1 below shows the national breakdown of water uses.

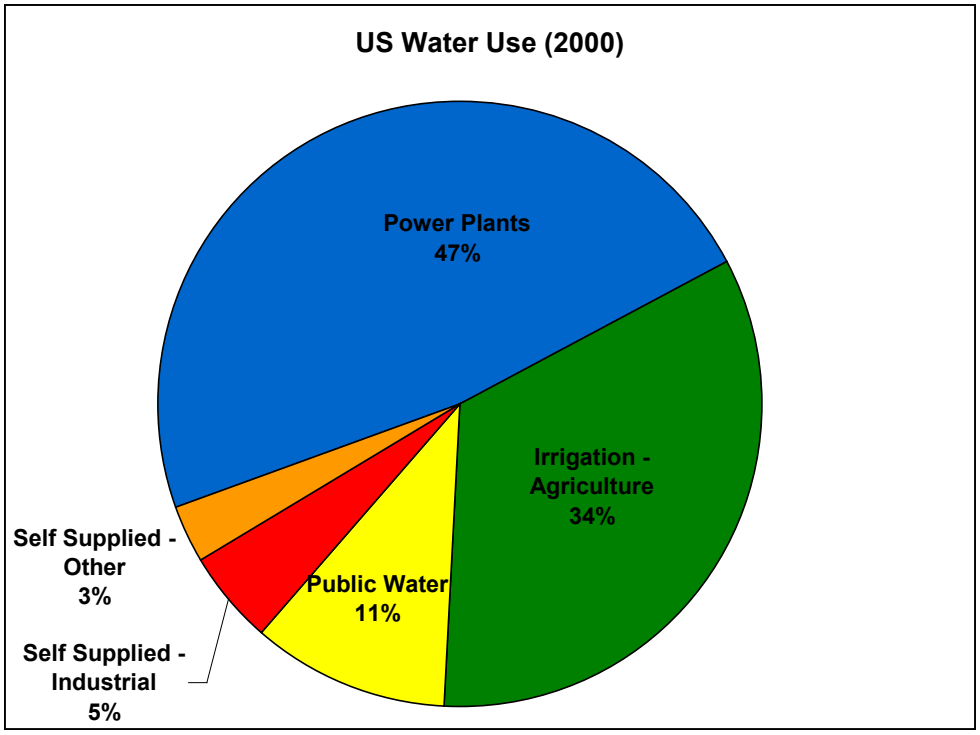


Figure 1: Total United States Water Use[1]

Public water supplies are often measured in gallons per capita per day (GPCD.) This is nothing more than the average daily supply divided by the service population. The national average for public water supplies is 179 GPCD, the California statewide average is 203 GPCD. California has the 15th highest per capita public water consumption in the country. Generally, the states with the highest water consumption are in the south and west, where there is a year round growing season and larger average home sites.

Water Use in the Home

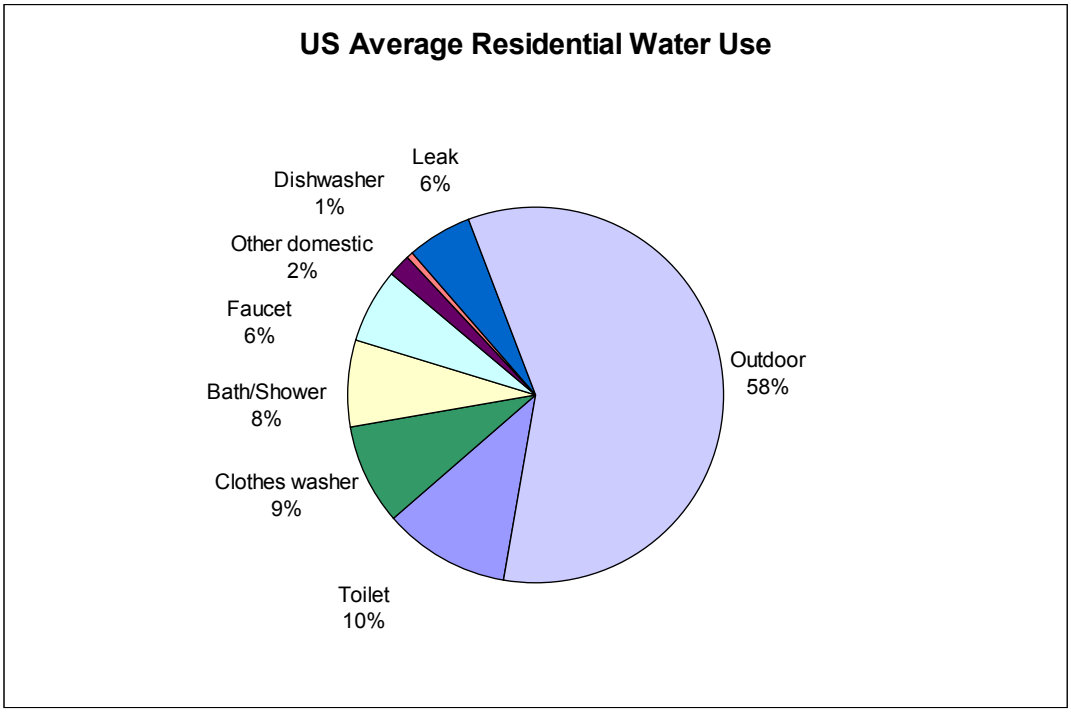

Figure 2: Average US Residential Water Use[2]

In the United States, residential water use is typically dominated by landscape water use and California is no exception. Figure 2 above shows the relative importance of various water uses throughout the home. There is a wide amount of variability in the above percentages. How much water an individual home will use is largely dependent on four factors: the number of residents; the types of fixtures (toilets, showerheads, faucets); the size of the home lot, and the type of landscaping (turf and pools using the most water.)

Indoor Water Use

The 2008 California Green Building Standards Code (CGBSC)[3] sets new standards for the flow rate of fixtures in new construction. The standards come into effect in 2011 and will call for a 20% reduction in indoor water use. The code also includes guidance on how to calculate the "baseline" indoor water use for a current new single family home. Table 1 lists the fixture flow rates and usage amounts assumed in the code for present day construction. The current fixture flow rates were set by the Federal Energy Policy Act of 1992, which became effective in 1994. Before that time, flow rates for these fixtures were much higher. In California, the 1980 plumbing code set showerhead flow rates at 2.5 gallons per minute (gpm) and toilet flow rates at 3.6 gallons per flush (gpf.) Before 1980, those values were typically 3.5 gpm and 5.0 gpf respectively. Table 2 shows the historical flow rates of showers, faucets, and toilets, as well as the flow rates which will become effective in 2011. Low flow faucets and showerheads should not add to the cost of the home. Currently, there is an approximately $50 premium on low-flow toilets, but that price has dropped dramatically over the past two years.

FIXTURE TYPE	FLOW RATE[2]	DURATION	DAILY USES	OCCUPANTS[3, 4]
Showerheads	2.5 gpm @ 80 psi	8 min.	1	X
Showerheads residential	2.5 gpm @ 80 psi	8 min.	1	X
Lavatory faucets residential	2.2 gpm @ 60 psi	.25 min.	3	X
Kitchen faucets	2.2 gpm @ 60 psi	4 min.	1	X
Replacement aerators	2.2 gpm @ 60 psi			X
Wash fountains	2.2 [rim space (in.) / 20 gpm @ 60 psi]			X
Metering faucets	0.25 gallons/cycle	.25 min.	3	X
Metering faucets for wash fountains	.25 [rim space (in.) / 20 gpm @ 60 psi]	.25 min.		X
Gravity tank type water closets	1.6 gallons/flush	1 flush	1 male[1] 3 female	X
Flushometer tank water closets	1.6 gallons/flush	1 flush	1 male[1] 3 female	X
Flushometer valve water closets	1.6 gallons/flush	1 flush	1 male[1] 3 female	X
Electromechanical hydraulic water closets	1.6 gallons/flush	1 flush	1 male[1] 3 female	X
Urinals	1.0 gallons/flush	1 flush	2 male	X

Fixture "water use" = flow rate × duration × occupants × daily uses

1. Except for low-rise residential occupancies, the daily use number shall be increased to three if urinals are not installed in the room.
2. The flow rate is from the CEC Appliance Efficiency Standards, Title 20, *California Code of Regulations*; where a conflict occurs, the CEC standards shall apply.
3. For low rise residential occupancies, the number of occupants shall be based on two persons for the first bedroom, plus one additional person for each additional bedroom.
4. For nonresidential occupancies, refer to Table A, Chapter 4, 2007 *California Plumbing Code*, for occupant load factors.
5. Use worksheet WS-1 to calculate base line water use.

Table 1: Table 603.1 of the 2008 California Green Building Standards Code

Fixture and Appliance Standards Over Time					
	1975	1980	1992	2009	2011
Shower (gpm)	3.5	**2.5**	2.5	2.5	**2.0**
Toilets (gpf)	5.0	**3.6**	**1.6**	1.6	**1.28**
Faucets (gpm)	2.5	2.5	2.5	**2.2**	**1.8**
Clothes Washers (gal/cu. Ft.)	15	15	15	**8.5**	**6**

Table 2: Flow Rates of Fixtures Over Time

The CGBSC, however, only covers showers, faucets, and toilets. The code does not provide baseline guidance for outdoor water use, nor does it provide guidance for clothes washer water use, which, as shown in Figure 2, is significant.

An average top loading clothes washer uses between 40 and 45 gallons per wash[4]. A horizontal axis washer can use between 15 and 30 gallons. Appliance standards currently effective in California limit the amount of water to 8.5 gallons per cubic foot of capacity. In 2010 this number will drop to 6 gallons per cubic foot. The average clothes washer capacity is 3 cubic feet, meaning a new clothes washer will average 18 gallons per wash. Studies have shown, the average household does between 300 and 400 loads of laundry per year[5]. Table 3 combines the fixture assumptions provided by the CGBSC with the assumptions on clothes washer usage to determine the estimated indoor water use for a new three bedroom home. Table 4 compares the water use of homes built prior to 1980, prior to 1994, the present day, and after 2011.

Table 4: Indoor Water Use Over Time

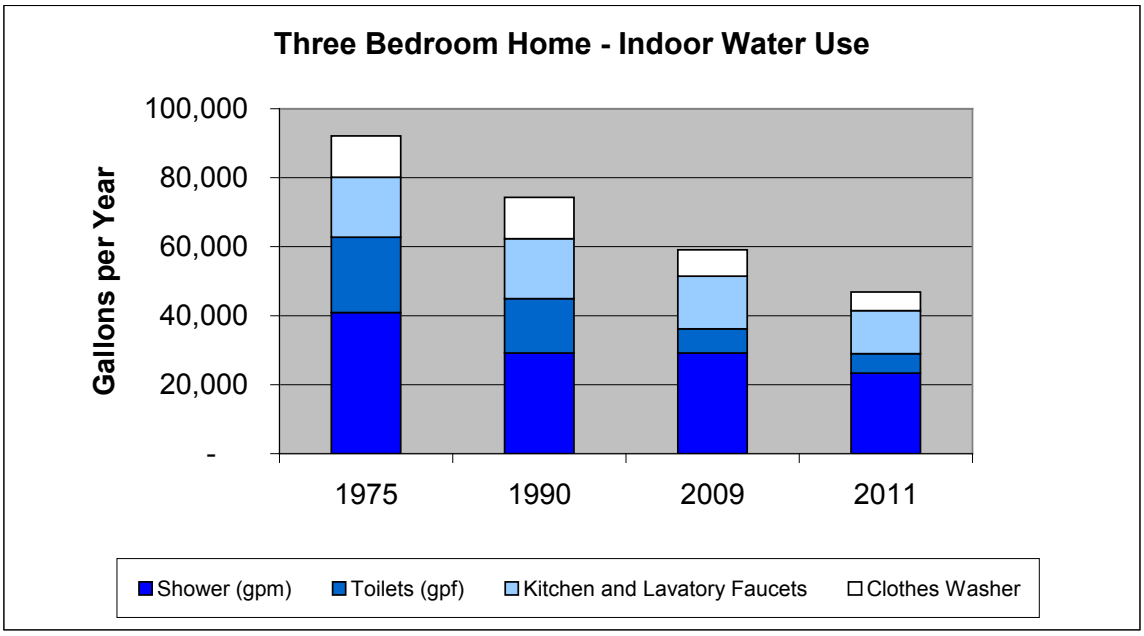

Figure 3: Indoor Water Use Over Time

Outdoor Water Use

The methods detailed in the California Department of Water Resources' recently published Model Landscape Ordinance[6] will be used to estimate outdoor water usage. The ordinance provides the formula listed in Equation 1 in order to determine the water needed by a given landscape.

$$LandscapeWater = (ETo)x(0.62)x(Area)x(ETAF)$$

Equation 1: Outdoor Water Use

In Equation 1, ET_o is the reference evapotranspiration. This is the amount of water, in inches, a specific species of grass requires in a specific climate. This number varies from city to city throughout the state, and the numbers are published in the Model Ordinance. The ET_o for Sacramento is 52 inches; for Monterey, which is much wetter and cooler, the ET_o is 36 inches. Needles, on the Arizona border, has the highest ET_o in the state at 92 inches. The median ET_o for the state is 50 inches. The complete list of the ET_o for all cities in California is available in Appendix A.

The number .62 is a conversion factor needed for the equation to output the water needed in gallons. The "Area" is the square footage of landscaping. For the purposes of this report, the average landscaped are of a single family home will be assumed to be 4000 square feet[7].

ETAF stands for evapotranspiration adjustment factor. This is a number that incorporates the specific plant type as well as the irrigation efficiency of the system[8]. The Model Ordinance uses a default value of 0.8 for the average existing California landscape. Given the assumptions made above, the landscape of an average single family home in California will require just shy of 100,000 gallons per year. Landscapes designed under the ordinance must have an ETAF of 0.7 or lower. This is accomplished through the greater use of plants that require less water. These landscapes will need 87,000 gallons of water per year, on average, a savings of 13,000 gallons. Meeting the requirements of the Model Ordinance should not add much cost to the installation of landscaping. However, there may be additional costs due to the time needed to calculate the water use of the landscaping in order to determine compliance.

It is rarely the case, however, that a landscape gets exactly as much water as it "needs"; more often than not, homeowners over water their lawn. One of the most detailed studies on the watering habits of homeowners was conducted by the Irvine Ranch Water District[9] (the ET_o for Irvine is conveniently right at the state average, making it well suited to evaluating landscaping water use).

The study concluded there was a savings potential in excess of 43 gallons per household per day, or roughly 16,000 gallons per year, if residents would not over water their lawn. The study examined two methods of changing homeowner behavior: mailing homeowners periodic postcards that carried suggested watering schedules; and installing weather based irrigation controllers (WBIC) that automatically adjust the irrigation system depending on current weather conditions (turning the sprinklers off after it has just rained). Mailing out the watering schedules captured 30% of the potential

[6] http://www.water.ca.gov/wateruseefficiency/landscapeordinance/
[7] http://www.epa.gov/WaterSense/docs/app_b508.pdf
[8] ETAF is the Plant Factor (PF) divided by the Irrigation Efficiency (IE.) Most turf grass has a PF of 0.8 or higher, while drought tolerant shrubs have a PF of 0.3 or lower. The PF numbers for specific plants can be looked up in the Water Use Classification of Landscape Species (WUCOLS) database, published by the University of California Cooperative Extension, the Department of Water Resources and the Bureau of Reclamation, 2000. Irrigation Efficiency is the percentage of water that leaves the sprinkler or irrigation device and actually lands on plants that need watering. Poorly designed spray head irrigation can have an IE of less than 0.6.
[9] http://www.irwd.com/Conservation/FinalETRpt[1].pdf

savings, 4,800 gallons per year. The WBICs captured 85% of the savings, 13,600 gallons per year. Because of their efficacy, WBICs are included in the Model Landscape Ordinance, and are likely to be added to the CGBSC. WBICs range on price from $150 to $350 dollars compared to a standard irrigation controller which is generally less than $50. Many water districts, however, provide rebates or incentives for the installation on WBICs.

When factoring in over watering, an "average" California landscape will consume approximately 115,000 gallons per year, a home which meets the requirements of the Model Landscape Ordinance will use approximately 89,000 gallons per year. This represents a savings of 26,000 gallons per year.

Combining the outdoor water savings with indoor water savings, a home built in 2011 will use 38,000 gallons of water less per year.

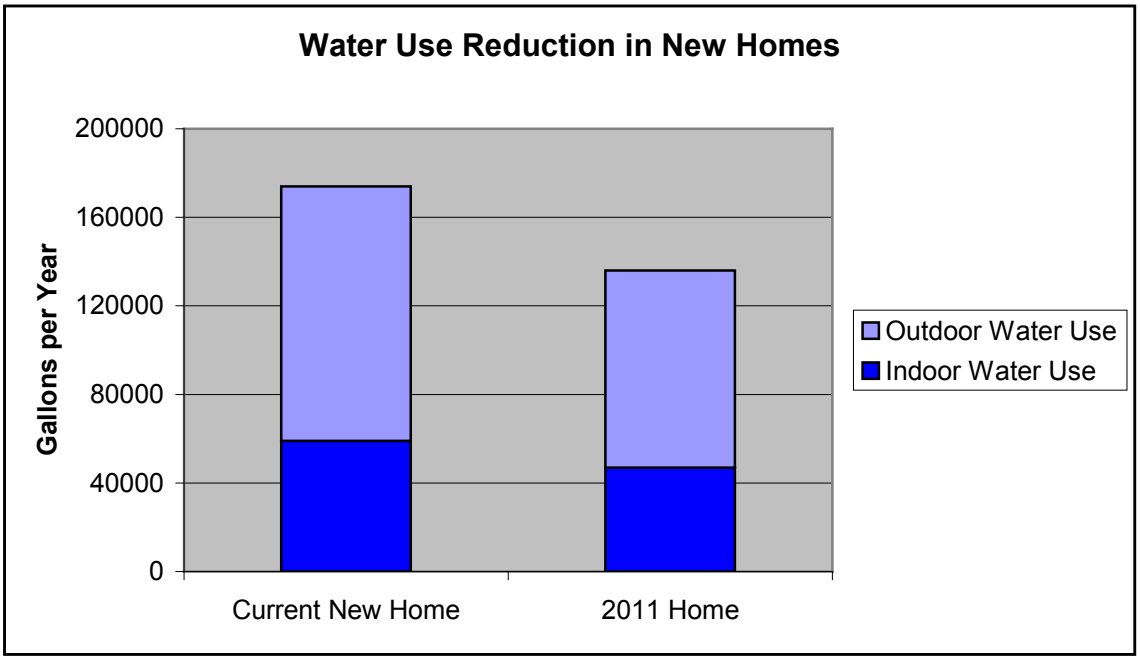

Figure 4: Water Use for New Three Bedroom Home

Wasted Water

Every morning, millions of gallons of water are wasted as homeowners wait for hot water to reach their showers. Studies have shown the average home with a conventional plumbing system uses an extra 10,000 gallons per year waiting for hot water[10]. Two systems which greatly reduce this waste are recirculation systems and parallel piping systems. A recirculation system is a pump that moves hot water through the pipe system so that it is ready when the fixture is tuned on. Recirculation systems come in three main varieties: always on; timer controlled, where the pump is set to run every day at specified times (at 6:15 am if you normally shower at 6:30;) and on demand, where the homeowner manually activates the pump. Recirculation systems eliminate nearly all the water loss while waiting for hot water. They cost approximately $500 to install, and do use additional energy, especially recirculation systems that are always on.

Parallel piping is a plumbing system that uses smaller diameter plastic pipes to run directly from the hot water fixtures to the water heater. Because these pipes have a smaller diameter, they hold a smaller volume of water that needs to be cleared before hot water arrives. These systems save on average, 7,000 gallons of water per year. There is an additional materials cost to installing a parallel piping system, but this is often negated by lower labor costs as the installation is generally easier than a traditional structured plumbing system.

Savings Potential

California currently has over 7,500,000 single family homes, more than half of these homes were built before 1980, when the first plumbing standards came into effect. While many of these homes have likely had their fixtures updated at some point, others have not. These older homes represent a large source of potential water savings.

Year Built	Number of Units	Avg. Indoor Water Use	Avg. Outdoor Water Use
pre 60s	2,392,460	92,118	115,088
60s	1,143,459	92,118	115,088
70s	1,162,924	92,118	115,088
80s	1,135,153	74,306	115,088
90s	826,346	59,115	115,088
00s	889,181	59,115	115,088
Total	7,549,523		

Table 5: Homes Built by Year

Table 6 Provides the savings potential of various retrofit measures discussed above. Water numbers are in gallons per year.

Year Built	Number of Units	Avg. Indoor Water Use	Avg. Outdoor Water Use	Fixture Replacemet	Toilet Replacement	WBIC	Water Schedules	Recirculation System
pre 60s	2,392,460	92,118	115,088	22,375	16,294	13,491	4,762	10,000
60s	1,143,459	92,118	115,088	22,375	16,294	13,491	4,762	10,000
70s	1,162,924	92,118	115,088	22,375	16,294	13,491	4,762	10,000
80s	1,135,153	74,306	115,088	10,695	10,162	13,491	4,762	10,000
90s	826,346	59,115	115,088	8,614	1,402	13,491	4,762	10,000
00s	889,181	59,115	115,088	8,614	1,402	13,491	4,762	10,000
Total	7,549,523							

Table 6: Savings Potential of Retrofit Measures

[10] http://www.toolbase.org/PDF/CaseStudies/hot_water_distribution_TN_California_2004_paper.pdf

The costs of retrofitting existing home could vary widely. The following assumptions (Table 7) are made to determine the cost of retrofit packages.

	Cost/unit	Units/Home	Total Cost
Fixture Replacemet	$ 50	3	$ 150
Toilet Replacement	$ 250	3	$ 750
WBIC	$ 250	1	$ 250
Recirculation System	$ 500	1	$ 500

Table 7: Retrofit Package Costs

Replacing old showerheads is by far the most cost effective water conservation measure available. The new code requirements are also fairly cost effective. The cost increase for a new home to meet the 2011 standards is estimated to be $350: $50 for three toilets, and $250 for additional landscape design. However, the total savings potential for the new code is only applicable to new construction, which accounts for less than 2% of the total housing stock.

Upgrade Measure	Annual Savings per Dollar (Gal.)
Replacing 5 gpm Showerheads	224
Replacing 3.5 gpm Showerheads	107
New Code Requirements	95
Replacing 2.5 gpm showerheads	86
Installing WBIC	54
Replacing 5 gpf Toilet	22
Install Recirc. System	20
Replacing 3.6 gpf Toilet	14
Replacing 1.6 gpf toilet	2
